tages COMP 6651: Algorithm Design T

COMP 6651: Algorithm Design Techniques
Winter 2016 Mid-term Examination

Time: 1 hour 30 minutes

Student name: Kintian Wang

Student id: 400 1630

Notes:

- 1. This exam has 4 questions, each worth 5 marks, and has 8 pages. Read every question very carefully before attempting to solve it.
- 2. Answers must be short and precise yet complete. Verbose explanations may reveal flaws in your logic, which would incur penalties.
- 3. You do not need to give the pseudocode of any algorithm that we have studied in class, simply call it as a function/subroutine with the appropriate parameters.

5435

You may or may not wish to make use of the following facts:

(i)
$$\sum_{k=1}^{n} k = \frac{n(n+1)}{2}$$

(ii)
$$\sum_{k=1}^{n} k^2 = \frac{n(n+1)(2n+1)}{6}$$
.

(iii)
$$\log_a a^i = i$$

(iv)
$$\log_b a = \frac{\log_c a}{\log_c b}$$

(v) Master Theorem: Let $a \ge 1$ and b > 1 be constants, let f(n) be a function and let T(n) be defined on the non-negative integers by the recurrence:

$$T(n) = aT(n/b) + f(n)$$

where we interpret n/b to mean either $\lfloor n/b \rfloor$ or $\lceil n/b \rceil$, Then T(n) can be bounded asymptotically as follows:

- (a) If $f(n) = O(n^{\log_b a \epsilon})$ for some constant $\epsilon > 0$ then $T(n) = \Theta(n^{\log_b a})$.
- (b) If $f(n) = \Theta(n^{\log_b a})$ then $T(n) = \Theta(n^{\log_b a} \log n)$.
- (c) If $f(n) = \Omega(n^{\log_b a + \epsilon})$ for some $\epsilon > 0$ and if $af(n/b) \le cf(n)$ for some constant c < 1 and all sufficiently large n then $T(n) = \Theta(f(n))$.

(vi) Sorting and Selection Algorithms and their Complexities

Algorithm	Worst-case time	Average-case time	Extra Space
Linear search	$\Theta(n)$	$\Theta(n)$	$\Theta(1)$
Binary search	$\Theta(\log n)$	$\Theta(\log n)$	$\Theta(1)$
Quicksort	$\Theta(n^2)$	$\Theta(n \log n)$	$\Theta(\log n)$
Mergesort	$\Theta(n \log n)$	$\Theta(n \log n)$	$\Theta(n)$
Heap sort	$\Theta(n \log n)$	$\Theta(n \log n)$	$\Theta(1)$
Insertion sort	$\Theta(n^2)$	$\Theta(n^2)$	$\Theta(1)$
Counting sort*	$\Theta(n+k)$	$\Theta(n+k)$	$\Theta(k)$
Minimum/Maximum	$\Theta(n)$	$\Theta(n)$	$\Theta(1)$
Median	$\Theta(n)$	$\Theta(n)$	$\Theta(\log n)$
k-th largest element	$\Theta(n)$	$\Theta(n)$	$\Theta(\log n)$

^{*} assuming that elements are in the range $[1, \ldots, k]$.

The state of the s

- 1. Solve the recurrence T(n) = 16T(n/4) + n.
 - (a) (2 marks) Use the master theorem to generate a guess. Show all your work, state what are $a, b, \log_b a, n^{\log_b a}, f(n)$, which case you are using, ϵ if applicable, and the solution in proper asymptotic notation.

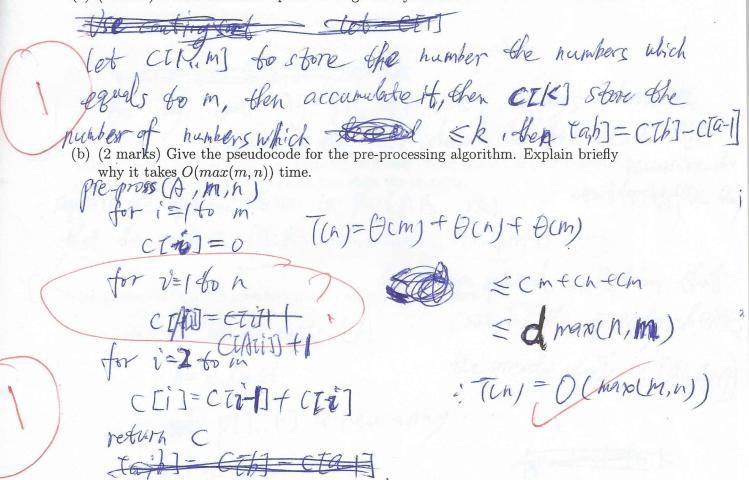

solution in proper asymptotic notation.

Vse master theorem $\alpha=1b$, b=4 logs=2 fin)=n $n^{\log n}=n^2$ $n^{$

(b) (3 marks) Prove an upper bound on T(n) using the substitution method. Your answer must be in O-notation. You do not need to prove a lower bound, and you may ignore floors and ceilings.

Suppose $T(n) \le Cn^2 - h$ C70 Substitution $T(n) = 16T(\frac{h}{4}) + h \le 16(\frac{cn^2 - h}{16} - \frac{h}{4}) + h$ $= cn^2 - 3h$ $= (cn^2 - h) - 2h < cn^2 - h$ $\therefore T(n) = O(n^2)$

- 2. You are given an unsorted array A of n elements containing integers in the range 1 to m. You want to answer queries of the sort "How many array elements are in the range [a,b]?" where a and b are integers. Design an O(max(m,n)) algorithm to preprocess the array so that any such query can be answered in O(1) time.
 - (a) (1 mark) Give a brief description in English of your idea.

(c) (2 marks) Give the pseudocode for the query-response algorithm. Explain briefly why it takes O(1) time.

a minimum sized set of unit intervals $\{[p_i, p_i + 1] \mid 1 \le i \le k\}$ that contain the points. For example, suppose the given set of points is {2.5, 3.3, 5, 5.9, 6.3}, then an optimal solution is the set of intervals $\{[2.5, 3.5], [4, 5], [5.5, 6.5]\}$, as it has only three intervals, and there is no solution covering the set of points that uses only two intervals. There are many other optimal solutions. However $\{[1.5, 2.5], [3, 4], [5, 6], [6, 7]\}$ is a non-optimal solution as it uses four intervals. (a) (1 mark) Describe in words a greedy heuristic to solve the problem. input the charge For any input Aj= {aj, 96+1::an}, always choose the (b) (2 marks) State precisely the property of greedy choice specific to your heuristic. pe curpine do There is no need to give a proof, just state the property. next-for a cak. an suppose the optimal solution is P=(P,P2...PK) flat de unit is PIPIPI+12, In, R+12. IPK, PK+12} (c) (2 marks) Give the pseudocode for your greedy algorithm. shile i'=n

if a[i]=p[i]+ $if i \le n \le i$ $k = k^{5} + 1$ return P.K

3. Given a set of points a_1, a_2, \ldots, a_n on a line, with $a_1 \leq a_2 \leq \ldots \leq a_n$, you want to find

- 4. We say that a string is a palindrome if it reads the same backwards and forwards. Some examples of palindromes are the strings a, aabbaa, racecar and malayalam. We want to design an efficient algorithm to find the longest palindrome that is a subsequence of a given input string. For example, given the input character, your algorithm should return carac. Assume you are given an array A[1..n]. Give a recursive formulation for c[i,j], which is defined to be the length of the longest palindrome that is a subsequence of the sub-array A[i..j]. Assume that $c[i,j] = -\infty$ if i > j.
 - (a) (1 mark) For $1 \le i \le n$, what is c[i, i]?

(b) (1 mark) For $1 \le i \le n - 1$, what is c[i, i + 1]?

(c) ((2 marks) For $1 \le i < j \le n$, what is c[i, j]?

(d) (1 mark, only if the previous part is correct) State the time complexity of implementing your recursive formulation using a dynamic programming bottom-up method, and give a brief explanation. There is no need to give the pseudocode.

Using bottom-up method, we have a table of n^2 to fill, and each entry need O(1) time. So the time completity is $O(n^2)$
